

SaaS Product & Customer Analytics

Process Guide — from customer data to retention and revenue decisions

1. Start with the business problem

A SaaS company needs to grow recurring revenue while reducing preventable churn. The analyst's job is to connect revenue outcomes to customer behavior and identify where Customer Success or Product teams should act.

2. Build the metric tree

Start with MRR and active customers. Then calculate ARPA, logo churn, revenue at risk, plan-level performance and cohort behavior. Add product usage and support metrics to explain customer health.

3. Join the customer lifecycle

Accounts provide who the customer is. Subscription snapshots provide recurring revenue. Feature usage provides engagement. Support tickets provide service experience. These tables are joined through `account_id`.

4. Diagnose churn

Do not stop at an overall churn percentage. Break churn down by plan, industry, acquisition channel and customer characteristics. Then compare product usage and support experience between active and churned customers.

5. Quantify business impact

A 10% churn rate does not tell management how much money is exposed. Revenue-at-risk translates churn into MRR/ARR and helps prioritize high-value customers.

6. Turn correlation into an action

If low engagement and high support burden are associated with churn, create a health score and give Customer Success a prioritized list. Treat this as a signal, not proof of causation.

7. Power BI

Use one executive page for MRR and churn, one retention page for cohorts and plan performance, and one customer-health page for usage, support and revenue at risk.

Current project snapshot

Metric	Result
Accounts	1,200
Overall churn	7.1%
Latest monthly MRR	\$8,993,699
MRR at risk from churned accounts	\$493,741
Highest-churn plan	Business (8.4%)

The project is deliberately synthetic and reproducible. That makes it safe for a portfolio while preserving the structure of a real SaaS analytics environment.
